Product list application

Create a basic prototype that will have the following parts:

1. List of all Products (home page)
   - A simple vertical list of products. Each product name can be clicked which will take user to a "Product Detail" screen for the clicked item.

2. Product Detail Screen
   - It will list Product details: name, number, description, images. All fields will be readonly. Images field will list all images as links..
   - There will be an Update button. Clicking the button will:
     - Remove / hide the Update button from the page.
     - Enable edition of all fields of the currently displayed Product Detail.
     - Two buttons will be added: Save and Cancel (Save will persist the changes and Cancel will discards all changes and disable edition).

Technical requirements

- You can use any bootstrap project/toolkit/framework you want.
- All products must be persisted, so that the are available on next user visit. For that you can use any technique.
- Data must be stored and retrieved in JSON format (see Appendix 1 for JSON example).
- You are not expected to implement Delete or Create functionalities.

Extra points for

- Use of promises.
- Use of ES2015 or TypeScript.
- Use of Flux for state management.
- Making it look production ready (don't spend too much time on styling - functionality first).

Acceptance Criteria

It is important that you stick to what you know and what you're good at.

However, this is the minimum you must provide:

1. Working list of Products (as specified above).
2. Working display functionality of the Product Detail Screen.
3. We will accept a submission with update not fully functional, but obviously this will have impact on your final result.
